Reliability of Spinal Palpation for Diagnosis of Back and Neck Pain

A Systematic Review of the Literature

Michael A. SefÞnger, DO,* Wadie I. Najm, MD, Shiraz I. Mishra, MD, PhD,à Alan Adams, DC, MS,¤ Vivian M. Dickersobinda@,S. Murphy, MLIS,¦ and Sibylle Reinsch, PhD**

Study Design. A systematic review. Objectives. To determine the quality of the research and assess the interexaminer and intraexaminer reliability of spinal palpatory diagnostic procedures.

Summary of Background Data. Conflicting data have been reported over the past 35 years regarding the reliability of spinal palpatory tests.

Methods. The authors used 13 electronic databases and manually searched the literature from January 1, 1966 to October 1, 2001. Forty-nine (6%) of 797 primary research articles met the inclusion criteria. Two blinded, independent reviewers scored each article. Consensus or a content expert reconciled discrepancies.

Results. The quality scores ranged from 25 to 79/100. Subject description, study design, and presentation of results were the weakest areas. The 12 highest quality articles found pain provocation, motion, and landmark location tests to have acceptable reliability (K 0.40 or greater), but they were not always reproducible by other examiners under similar conditions. In those that used kappa statistics, a higher percentage of the pain provocation studies (64%) demonstrated acceptable reliability, followed by motion studies (58%), landmark (33%), and soft tissue studies (0%). Regional range of motion is more reliable than segmental range of motion, and intraexaminer reliability is better than interexaminer reliability. Overall, examinersÕ disciplinerall,a regional and segmental motion, paraspinal soft tissue abnormalities, and tenderness on provocation. The ability to arrive at an accurate palpatory assessment depends mainly on the validity and reliability of the palpatory tests used.

Although validity and reliability are often used interchangeably in the literature, they are not synonymous. Validity is the accuracy of a measurement of the true state of a phenomenon⁹. Reliability measures the concor dance, consistency, or repeatability of outcomes⁹.

Over the past 30 years, scientists with diverse professional training have investigated the validity and/or reliability of spinal palpatory tests used to diagnose nonspeci c back pain.^{11–13} Several narrative reviews of the literature on spinal palpatory diagnostic procedures have been published.14-17 However, only two systematic reviews of reliability studies of spinal palpatory tests have been published. One is a limited review of chiropractic literature on palpatory diagnostic procedures for the lumbar-pelvic spine¹⁸; the other¹⁹ focused on the reliability of sacroiliac joint palpatory tests. The reliability of spinal palpatory diagnostic procedures for neck and back problems remains unclear. There is no comprehensive systematic review of the literature on the reliability of cervical, thoracic, and lumbar spinal palpatory diagnostic procedures.

The authors performed a systematic review of original research articles, from all disciplines, published in peerreviewed journals in order to assess the quality of the literature and answer the clinical question:" What is the intra- and interexaminer reliability of spinal palpatory diagnostic procedures?

Materials and Methods

A multidisciplinary team conducted the systematic review at the Susan Samueli Center for Complementary and Alternative Medicine (University of California, Irvine), between October 2001 and December 2002. The research team included expertise in database searches, clinical research, evidence-based medicine, research design, and statistics methodology. The clinicians represented content area experts in osteopathic, chiropractic, and family medicine/primary care.

A comprehensive strategy, including the exploration of 13 online databases and a manual search of appropriate literature, guided the search for pertinent articles that addressed the study question. Articles were limited to human studies published in peer-reviewed journals or dissertations published between January 1, 1966 and October 1, 2001. All databases were searched using a basic search template. When appropriate, minor modi cations to the basic search template were made to optimize the search strategy in individual databases. The 13 databases included: PubMed MEDLINE, MANTIS, MD Consult, Web of Science, EMBASE, CINAHL, BIOSIS Preview, Index to Chiropractic Literature, OSTMED, OCLC FirstSearch, Digital Dissertation, PEDro, and Cochrane. Selection of these databases was determined by the availability of online resources accessible from our institution and af liated institution libraries, as well as potential inclusion of articles from osteopathic medicine, allopathic medicine, chiropractic medicine, manual medicine, and physical therapy. The manual search included gleaning references cited in studies selected from the online search, and

reliability studies. Thus, the total number of studies included in the 49 articles is 53. Descriptions of the characteristics of the studies are summarized in Table 1.

Paired reviewers initially disagreed on the quality score of 16 (33%) of the 49 articles. Quality scores of the 49 articles ranged from 25 to 79 of 100. The authors compared quality scores of articles in the top quartile (67.5–79) to those in the bottom quartile (25–47). No correlation between quality score and year of publication, examiners' disciplines (clinical degree or specialty training), or procedure evaluated was found. All studies were lacking in description of subjects. Study design, description of study conditions and examiners' professional training, data analysis, and presentation of results were the weakest areas in the lower quality studies.

Interestingly, symptomatic (back or neck pain) subjects were recruited only in 14 (26%) of the 53 studies, and both symptomatic and asymptomatic subjects were recruited in only 9 of 53 (17%). Additionally, two studies assessed the effect of hypertensive subjects on the reliability of palpatory ndings.^{41,42}

The authors synthesized the data only from the higher quality articles (quality score 67.5 of 100 or greater). Most (two thirds) of the higher quality articles used the more rigorous kappa or weighted kappa measure of as-

258.671

The majority of spinal palpatory diagnostic tests demonstrated low reliability. Data from the higher quality studies (quality score 67.5 of 100 or greater) showed acceptable reliability for the following spinal palpatory diagnostic procedures: 1) interexaminer regional range of motion of the cervical spine⁴⁴; 2) intraexaminer thoracic and lumbar segmental vertebral motion test⁴⁵; 3) interexaminer pain provocation at a) L4–L5 and L5– S1,⁴⁶ b) lumbar paraspinal myofascial trigger points (be tween trained examiners only),⁴⁷ c) the cervical spine,^{48,49}

Table 3. Quality Scores, Study Characteristics, Intra- and InterEx Reliability for Pain Provocation Tests

There are informative trends noticeable among the higher quality quartile studies that used the same statistical analysis. In those studies that used kappa statistics, a higher percentage of the pain provocation studies (7 of 11; 64%) demonstrated acceptable reliability followed by motion studies (7 of 12; 58%), landmark studies (1 of 3; 33%), and soft tissue studies (0 of 11; 0%). No spinal

Table 5. Quality Scores, Study Characteristics, Intra- and InterEx Reliability for Landmark Tests

cedures. In a systematic review of the content validity of spinal palpatory tests, the authors found that pain scales were one of only a few validated instruments that can be used in these types of studies⁶.

The spinal examination, with its small joints and limited mobility, may be more dif cult for most clinicians than more prominent joints. The larger joints of the extremities fare slightly better (i.e., physical therapists assessing shoulder motion restriction, kappa 0.62– 0.76).⁵⁷ However, the smaller joints of the extremities, like the vertebral spine, are less reliablei.(e., kappa 0.24–0.60 among rheumatologists palpating for hard tissue enlargement of hand and nger joints).⁵⁸

Evaluation of the reliability of physical examination procedures in general poses a number of methodologic challenges. Examiner bias and inconsistency create variability in procedures. Although palpation for pedal pulses has medium to high reliability (kappa 0.54–0.87),⁵⁹ many physical examination procedures used commonly in clinical practice have low to medium reliability. ^{60,61} This includes lung auscultation (kappa 0.32 for bronchial breath sounds and 0.51 for wheezes)⁶² and heart auscultation (31%–72% agreement among physicians).⁶³

The primary research articles on the reliability of spinal palpatory procedures are dif cult to compare due to variability in the palpatory tests, terminology, research design, study conditions, and statistical analysis used. The

quality scoring instrument helped to evaluate the relative value of their results. The quality assessment form can also provide a template with which future higher quality reliability studies can be designed (Tables 6 and 7).

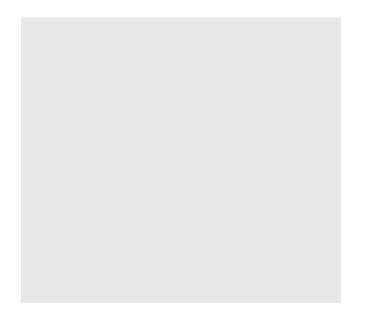

Limitations of this review include the retrospective design, the search strategy, databases used and article quality scoring. The authors conducted a retrospective review with current standards and expectations for scienti c rigor that might not have been expected at the time these studies were conducted and published. Authors and indexers are not always on the same page when choosing titles and keywords.²⁰ Online database searches were inadequate in locating all articles that met

the inclusion criteria.²⁰ Content expert and selective manual searches were necessary imding many of the articles²⁰. The article reviewers each had different educa tion and training backgrounds, accounting for the initial disagreement in scoring in one third of the articles. Before reviewer consensus, there was variability in interpretation of the quality scoring instrument terms as well as in judgments regarding how well an article addressed the issues being evaluated. In using a quality assessment instrument, some quality scoring criteria are more detailed/ differentiated than others, which introduces an inherent bias. Scores/assigned weights may be biased toward rigor of research methodology and presentation. Since the

quality assessment instrument focused on the internal validity of the studies, the quality scores cannot be extrapolated to measure the studiessigni cance or impact (in terms of ndings, relevance to the discipline).

There are several strengths, however. The authors formed a multidisciplinary team, paying special attention to minimizing bias by the Doctor of Osteopathic Medicine and Doctor of Chiropractic on our team who did not review studies in their respective professions. The authors combined information (studies) obtained from different professions (PT, DO, DC, MD) in a systematic

manner. The quality assess siection (in a) manner. The quality assess siection (in a constraint of the second strain of the second stra
